Social Media Users	Proportion of Twitter users per one thousand inhabitants. Source: own elaboration from data collected with the Twitter API (see Section 3.1).				
Election Within 12 Months	Is the country holding an election within the next twelve months? Source of election dates: IFES Election Guide.				
Unfavorable polls (NELDA)	Were there reliable polls that indicated popularity of ruling political party or of the candidates for office before elections AND were they unfavorable to for the incumbent?				
Index of Social Unrest (ICEWS)	Source: NELDA25 and NELD26 (Hyde and Marinov, 2011) Logged count of events of civil society towards government that have a negative in- tensity value (hostile events). Source: ICEWS (Lautenschlager, Shellman, and Ward, 2015).				
Polity IV Score	Democracy score (Polity2 score), from -10 to 10. Source: Polity Project (Jaggers and Gurr, 1995).				
Adoption by K=4 Nearest Neighbors (1 lag)	Count of neighbors with active social media account, among 4 countries whose capitals are closest to the country. Source: own elaboration from social media users variable and GeoDist Database (Mayer and Zignago, 2011)				
Population, in 1000s (log)	Source: New Maddison Project Database (Bolt and Zanden, 2014)				

Variable	Description
Electoral Competition	Index computed as the sum of NELDA3 (opposition allowed), NELDA4 (more than
(NELDA)	one party legal), NELDA5 (a choice of candidates in the ballot), NELDA11 (no concerns
	about elections being free and fair), and NELDA12 (incumbent or ruling party not
	confident of victory before elections). Source: (Hyde and Marinov, 2011).
Riots and Protests After	Were there riots and protests after the election?. Source: NELDA29 (Hyde and Mari-
Election	nov, 2011).
Freedom of Expression (FH)	Freedom and independence of the media and other cultural expressions, ability of the
	people to engage in private (political) discussions without fear of harassment or arrest
	by the authorities, etc. Source: Freedom House.

Table 1: Operationalization and source of variables used in analysis

Validation of variable measuring social media users

We measure social media adoption by the public by estimating the number of Twitter users by country and month. This measure of social media adoption exploits the possibility of collecting random samples of tweets with geographic coordinates attached with the fact that the date in which each Twitter account was created is public information for all users. Our first step was to collect a dataset of 130 million geolocated tweets sent by 7 million unique users between November 6th, 2013 at 00:00:00 GMT and December 5th, 2013 at 23:59:59 GMT. Tweets were captured using the Streaming API and the streamR package for R (Barberá, 2013) and a geographic bounding box that spans the entire globe.¹ Then, we classified each of these tweets according to the country from which they were sent, building upon the technique developed by Mocanu et al. (2013). Finally, we extracted the user information for each tweet, which contains the date when they created their account. Under the assumption that users are tweeting from the country they live in, we thus consider the distribution of creation dates as equivalent to the rate of adoption in each country.

The use of this variable to measure social media adoption presents three limitations. First, it does not measure the number of Facebook users, although in our analysis we assume that changes over time in Facebook and Twitter adoption by citizens are highly correlated. Second, geolocated

¹Given the limitations of the API (only up to 1% of all tweets sent at any given time can be accessed), these 130 million tweets represent a random sample of the approximately 300 million geolocated tweets that were sent during the same period. This number was estimated based on the "track limit errors" returned by the Twitter API, which indicate the number of tweets that were missed due to the 1% rate limit.

tweets are a small sample of the entire universe of tweets (Ajao et al., 2015), and since it is composed mostly of users posting messages from smartphones, it is likely to underestimate Twitter adoption, particularly in countries with lower income levels. We may also underestimate user adoption in autocratic countries where freedom of expression is restricted, and thus users may have an additional incentive to hide the location of their tweets. Despite these concerns, in our analysis we show that our results (or lack thereof) are robust to controlling for GDP per capita and a measure of freedom of expression and belief elaborated by Freedom House. Finally, the fact that users often tweet when they travel can induce measurement error.² Despite these limitations, as we now demonstrate, this measure provides a reasonable approximation to the rates of social media adoption by citizens in the different countries we consider.

Table 2 displays our estimates of the number of users per million inhabitants in a sample of countries, as of December 2013. Our results match the main results in Mocanu et al. (2013). We find that countries in the Arabian peninsula, as well as Turkey, Spain, United Kingdom, and the United States have the highest Twitter penetration. These results are consistent with Eurobarometer survey data, which places Cyprus, Spain, Ireland, and the United Kingdom among the top 10 European countries with highest self-reported usage of social networking sites.³ The countries with lowest proportion of Twitter users are mostly in central Africa, and they also include small nation states such as San Marino, Nauru, and the Vatican.

Figure 3 demonstrates that the speed at which Twitter became an important tool for communication varies across countries. Here, we display our estimates of Twitter adoption over time for a set of eight different countries with high Twitter penetration. English-speaking countries like United States and United Kingdom were early adopters, with high rates of Twitter use since 2009. Kuwait represents the opposite case: here the number of users per capita has been increasing exponentially since late 2012.

²For example, the fact that citizens tweet more during their holidays probably explains why Bahamas is one of the countries with the highest number of users per capita, as we report in Table 2.

³As an additional validation exercise, we compared our estimates of Twitter usage by capita in the 28 EU countries as of November 2012 with survey data from the Eurobarometer conducted that same month, which included a question regarding social media use. The correlation between our measure and the proportion of citizens who "use online social networks at least once a week" (QE3.6) is r = 0.63.

Robustness checks

Here, we explore the robustness of our main findings. First, in Table 3, we show that a more complex measure of electoral competition that aggregates different variables in the NELDA dataset (Hyde and Marinov, 2011) yields similar result: positive and significant in the models containing only variables related to electoral pressure, but losing its statistical significance once we control for variables measuring democratic levels. We find that an alternative variable measuring social unrest (the presence of riots and protest after the election, according to the NELDA dataset) is not a significant predictor of social media adoption, although this could be due to its lower degree of granularity (only a dummy variable, and not at the month level as ICEWS), and measuring unrest *after* the election. Finally, our result regarding the importance of democratic institutions also holds: freedom of expression and belief (from Freedom House) is a positive and significant predictor of social media adoption.

One concern with our analysis up to this point may be that we do not capture the interactive effect of electoral pressure and transparency/democracy. For instance, maybe only politicians in democracies are sensitive to electoral pressure. To test this argument, we split our sample into two groups, democratic and non-democratic countries, depending on whether their Polity IV Score is 6 or more, or less than 6. We then replicate our main analysis for these two groups of countries, with our two main measures of electoral pressure as shown in Table 4. We do not find that this effect is moderated by the level of democracy, as in all cases we find the coefficient of our electoral competition variables is not significantly different from zero. In contrast, the effect of social unrest remains positive and statistically significant in three of the four models.

In Table 5 we redo the analysis from Table 3 in the manuscript, but now we focus on the determinants of leaders adopting a personal ("Pers" column) versus institutional account ("Inst" column), and Twitter ("Tw" column) vs Facebook ("Fb" column account). The results largely confirm our main findings, and provide a bit more nuance. As in Table 3 in the manuscript, social unrest increases the probability that a leader will become active on social media platforms, which is consistent with the idea that protest may trigger leaders' incentives to improve their

communication practices in order to remain in power. Interestingly, leaders in more democratic regimes are more likely to adopt a personal account, but not an institutional account. This suggests that Transparency/Democracy Hypothesis effect is most strongly operating at the leader level. Leaders in democratic countries have an incentive to cultivate a personal, rather than institutional account–to increase their own stature. We find a similar pattern in the comparison of Twitter vs Facebook, with democracy more likely to drive adoption on the latter social media platform. This
